Reverse Engineering: Find the magic word to get the flag.

Overview:

A binary file name magic we have to enter the correct word to get the flag.

4.1 Load the binary

Load the binary into the Ghidra

4.2 Find relevant strings

• Open the **Defined Strings** view (right pane in your screenshots). Look for readable strings such as prompts: "Enter the magic word:" or garbled strings like `fcva`vpavg and PPFYhK#ALD"... that look encrypted/obfuscated.

```

4.3 Inspect the decompiled main

- In the decompiled code you will see:
 - o builtin_strncpy(secret, "<garbled>", 0xc);

```
    builtin_strncpy(flag, "<garbled>", 0x19);
    then xor(secret, 0x13, 0xb);
    and xor(flag, 0x13, 0x18);
    a printf("Enter the magic word: "); followed by fgets(...), strcmp(input, secret) and printf of flag if matched.
```

```

```

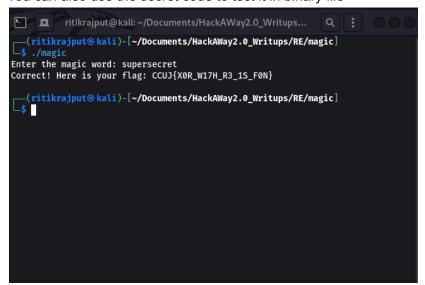

This tells us the binary copies two encoded strings into memory, XORs them in place with key 0×13 for given lengths, then compares expected secret with user input. So the secret and flag are present but XOR-obfuscated with a single-byte key.

4.5 Extract the encoded text and key

Copy the XOR string and make a python script to decode it

Reveal secret code as well as flag

You can also use the secret code to test it in binary file

Flag: CCUJ{X0R_W17H_R3_1S_F0N}
